Critical Care Nutrition: Systematic Reviews Jan 2022

9.2 Composition of Parenteral Nutrition: Type of lipids

Question: Does the type of lipids in parenteral nutrition affect outcomes in the critically ill adult patient?

Summary of evidence: A total of 21 level 2 studies (Nijveldt 1998, Lindgren 2001, Garnacho-Montero 2002, Garcia de Lorenzo 2005, Iovinelli 2007, Guo 2008, Wang 2009, Qu 2009, Barbosa 2010, Sabater 2011, Khor 2011, Zhao 2011, Pontes-Arruda 2012, Burkhart 2013, Gultekin 2014, Hall 2014, Wang 2014, Chen 2017a, Chen 2017b, Donaghue 2019 and Singer 2021) and 5 level 1 studies (Grecu 2003, Friesecke 2008, Gupta 2011, Umperrez 2012 & Grau Carmona 2014) were reviewed. For most of the studies, the focus of the investigation was on surrogate endpoints, but the studies were still included because they did report clinical outcomes such as mortality or infections.

Twenty-one trials using parenteral nutrition compared varying strategies of reducing omega-6 fatty acids from soybean oil (SO), and 5 trials used FO as a stand-alone supplement (Gupta 2011, Khor 2011, Zhao 2011, Burkhart 2014 and Hall 2015)

Omega-6 reducing lipid emulsions: SO/MCT or SO/OO

Four trials compared mixtures of SO (long-chain triglycerides [LCTs]) plus medium chain triglycerides (MCT) (SO/MCT), to a SO (LCT) emulsion (Nijveldt 1998, Lindgren 2001, Garnacho-Montero 2002 and lovinelli 2007). Additionally, 3 studies compared a mixture of soybean and olive oil (SO/OO, Clinoleic) to a SO/MCT mixture or SO (Garcia de-Lorenzo 2005, Umpierrez 2012 & Pontes-Arruda 2012). The trial by Pontes-Arruda include 3 groups: 1) multichambered bag (MCB) with OO/SO, 2) compounded PN with OO/SO and 3) compounded SO. In the meta-analysis, we have only included group 2 and 3 so as to evaluate the effect of OO and not effect of the MCB. The trial by Huschak was excluded from the meta-analysis because the PN strategies also varied by lipid and glucose composition

FO-containing lipid emulsions

The goal of FO-containing lipid emulsions was not only to lower amount the amount linoleic acid but to create a more favourable omega-3-to-omega-6 fatty acid ratio by adding a FO supplement to PN or either adding a FO containing lipid component to MCT/LCT (Lipoplus/Lipidem) or to blend of MCT/LCT and OO (SMOFlipid).¹

_

it is important to know that the fish oil enriched component of the two commercially available products Lipoplus and SMOFlipid comply with different European pharmacopeia (EP) monographs. Lipoplus complies with EP monograph 1352 "Omega-3-acid triglycerides" which is defined as a synthesized mixture of mono-, diand triesters of omega-3 acids. Sum of the contents of the omega-3 acids EPA and DHA expressed as triglycerides is not less than 45%. SMOFlipid complies with EP monograph 1912 "Fish oil, rich in omega-3 acids" which describes purified fish oil rich in omega-3 fatty acids. The monograph specifies that the content of EPA is not less than 13% and a content of DHA not less than 9%. Lipoplus contains-10% omega-3 acid triglycerides and SMOFlipid contains 15% fish oil, rich in omega-3 acids. Although omega-3 fatty acids are derived from natural sources (leading to slight variations in concentration), the actual concentrations of EPA and DHA in SMOFlipid and Lipoplus are comparable according to existing literature. Both products provide approximately the same omega-3-to-omega-6 (ratio of 1:2.5 to 1:2.6).

Seven trials of patients receiving parenteral nutrition compared lipid emulsions supplemented with fish oil (FO) (i.v. FO supplement Omegaven) to SO, MCT/SO or OO/SO (Grecu 2003, Friesecke 2008, Wang 2009, Gultekin 2014, Wang 2014, Chen 2017a, and Chen 2017b). The added FO emulsion was not specified in two trials (Guo 2009 and Qu 2009). Four trials compared a ready-to-use mixture of SO, MCT and FO² (SO/MCT/FO, Lipoplus) to SO/MCT (Barbosa 2010, Grau-Carmona 2014, Singer 2021) or SO (Sabater 2011), and 1 study compared another ready-to-use mixture of SO, MCT, olive oil (OO) and FO³ (SO/MCT/OO/FO, SMOFlipid) to LCT (Donoghue 2019).

Singer 2021 used an EN product enriched with fish oils in the intervention group, which was different than all other trials. The dose from parenteral fish oils was initially low (<0.05 g/kg/d on d1-5, >0.05 g/kg/d from d6) and most of the fish oils were derived from the enteral product so the effect of this trial was evaluated in a *sensitivity analysis* where it was excluded (See Table 2 on Fish Oil Dosing).

One study that compared an outdated long chain triglyceride (LCT) emulsion to another form of LCT (Kari 1998) was removed in the 2013 CPGs as it did not involve a soybean oil reducing strategy. The Wang 2008 study was replaced by a later version of the study by the same authors that had more patients i.e., Wang 2009. All of the studies had a goal of reducing the amount of omega-6 fatty acids in the setting of PN use.

Another 5 trials compared stand alone fish oil enriched IV lipid emulsions in patients fed as per usual clinical routine where the control patients received standard of care (Gupta 2011, Khor 2011, Zhao 2011, Burkhart 2013 and Hall 2014). These trials were analyzed separately.

Subgroup Analyses

We compared the effect of SO/MCT or SO/OO vs SO and FO-containing PN vs SO or SO/MCT or SO/OO. In addition, as Omegaven (10% lipid emulsion from pure fish oils) was used in 12 trials (7 were PN-fed trials and 5 were in the context of a stand-alone supplement), we performed a comparison of the trials of Omegaven vs. non-Omegaven fish oil containing strategies.

² FO component as Omega-3 Acid Triglycerides according to Pharm Eur Monograph 1352

³ FO component as Fish oil, Rich in EPA and DHA according to Pharm Eur Monograph 1912

Mortality:

Overall omega-6 fatty acid reducing strategy: When all the trials that used an omega-6 fatty acid sparing strategy, excluding those in which the FO supplements were given as a stand-alone intervention, were aggregated, the use of a lower omega-6 fatty acid strategy was not associated with a significant reduction in overall mortality (RR 0.91, 95% CI 0.76, 0.10. p=0.34, test for heterogeneity I² = 0%.; figure 1.1). However, a trend towards reduction in 28-day mortality was observed (RR 0.79, 95% CI 0.61, 1.02, p=0.07, I² = 0%; figure 2.1)

When sensitivity analysis was done without the Singer 2021 trial, a similar results was observed for overall mortality (RR 0.91, 95% CI 0.75, 1.11, p=0.36, test for heterogeneity $I^2 = 0\%$.; figure 1.2), and 28-day mortality (RR 0.77, 95% CI 0.59, 1.02, p=0.07, $I^2 = 0\%$; figure 2.2)

In subgroup analyses, neither SO/MCT or SO/OO vs OO (RR 0.89, 95% CI 0.65, 1.23, p=0.50, test for heterogeneity $I^2 = 0\%$.; figure 1.3) nor FO-containing PN vs SO or SO/MCT or SO/OO (RR 0.92, 95% CI 0.72, 1.16, p=0.47, test for heterogeneity $I^2 = 4\%$.; figure 1.3) had an effect on overall mortality. The test for subgroup differences were non-significant (p=0.91).

A trend towards reduction of 28-day mortality was found for FO-containing PN vs SO or SO/MCT or SO/OO (RR 0.74, 95% CI 0.54, 1,01, p=0.06, I² = 0%; figure 2.3). The test for subgroup differences were non-significant (p=0.50).

SO/MCT vs. SO: A meta-analysis of the studies of SO/MCT vs. SO showed no difference in overall mortality between the groups (RR 0.90, 95% CI 0.55, 1.48, p=0.68, heterogeneity I²=0%; figure 1.1). No studies reported 28-day mortality (figure 2.1)

SO/OO vs SO/MCT or SO: We observed no difference in overall mortality (RR 0.89, 95% CI 0.59, 1.34, p = 0.57, heterogeneity I²=0%; figure 1.1) and 28-day mortality (RR 0.91, 95% CI 0.56, 1.47, p = 0.69, figure 2.1) between the groups receiving the OO containing emulsions compared to SO/MCT or SO

FO containing PN vs. SO or SO/MCT or SO/OO: With respect to studies of FO enriched PN vs. SO or SO/MCT or SO/OO, no significant reduction in overall mortality was observed (RR 0.92, 95% CI 0.72, 1.16, p = 0.47, test for heterogeneity I^2 =4%; figure 1.1). In the sensitivity analyses without the Singer 2021 trial, the result was similar (RR 0.90, 95% CI 0.69, 1.18, p = 0.46, test for heterogeneity I^2 =12%; figure 1.2). However, a trend towards lower 28-day mortality was observed in the main (RR 0.74, 95% CI 0.54, 1.01, p=0.06, I^2 =0%; figure 2.1 and sensivity (RR 0.72, 95% CI 0.51, 1.01, p=0.05, I^2 =0%; figure 2.2) analyses.

Omegaven vs. other oils:

FO containing PN: Omegaven was associated with a significant reduction in overall (RR 0.68, 95% CI 0.48, 0.95, p=0.03, test for heterogeneity I²=0%; figure 1.4) and 28-day mortality (RR 0.63, 95% CI 0.41, 0.99, p=0.05, I²=16%; figure 2.4) while other fish oil emulsions had no effect on overall (RR 1.19, 95% CI 0.87, 1.62, p=0.27, test for heterogeneity I²=0%; figure 1.4) and 28-day (RR 0.91, 95% CI 0.56,

1.51, p=0.74, l² =0%; figure 2.4) mortality. The test for subgroup differences was significant for overall (p=0.02) but not 28-day (p=0.28) mortality..

In the sensitivity analyses that excluded the Singer 2021 trial, the effects of other fish oil emulsions on overall mortality were similar for both overall (RR 1.26, 95% CI 0.90, 1.77, p=0.18, test for heterogeneity $I^2 = 0\%$; figure 1.5) and 28-day mortality (RR 0.94, 95% CI 0.49, 1.83, p=0.86, $I^2 = 0\%$; figure 2.5), test for subgroup differences was significant in overall (p=0.01) but not 28-day mortality (p=0.33).

Stand-alone FO emulsion supplement vs. standard care: When these FO trials in which the control group received no lipids were aggregated, a trend towards significant reduction in overall mortality (RR 0.76, 95% CI 0.53, 1.10, p=0.14, test for heterogeneity I² =0%; figure 1.6), and a significant reduction of 28-day mortality (RR 0.60, 95% CI 0.36, 0.99, p=0.04, I² =0%; figure 2.6) were found. All aggregated trials used omegaven FO.

In studies that reported **ICU mortality**, no differences between groups were found in the overall and the subgroup analyses. None of the trial on standalone FO emulsion reported ICU mortality (figure 3.1 to 3.4)

In studies that reported **hospital mortality**, no differences no differences between groups were found in the overall and the subgroup analyses (figure 3.1-3.3). A trend towards reduced hospital morality was found when the 2 trials of stand-alone FO supplement were aggregated (RR 0.59, 95% CI 0.34, 1.04, p=0.07, I² =0%; figure 4.4)

Infections:

Overall omega-6 fatty acid reducing strategy: When all 7 studies that used an omega-6 fatty acid sparing strategy were aggregated, the use of a lower omega-6 fatty acid emulsion had no effect on infections (RR 0.94, 95% CI 0.70, 1.26, p = 0.68, I²=32%; figure 5.1).

In subgroup analyses, **SO/OO vs SO/MCT or SO** were associated with a trend towards an increase in overall infections (RR 1.23, 95% CI 0.92, 1.63, p=0.16, $I^2 = 0\%$.; figure 5.1) while **FO-containing PN** were associated with a significant reduction in infections (RR 0.65, 95% CI 0.44, 0.95, p=0.03, $I^2 = 0\%$.; figure 5.1). There was a significant difference between the two subgroups (p=0.008).

Omegaven vs. other fish oils:

FO enriched PN: When the data from 3 studies of Omegaven were aggregated, there was no effect on overall infections (RR 0.77, 95% CI 0.44, 1.36, p=0.37, I²=0%; figure 5.2) while in one study a significant reduction in infections was seen in the group receiving fish oil emulsion other than Omegaven (Grau-Carmona 2014, RR 0.56, 95% CI 0.34, 0.94, p=0.03; figure 5.2). Test for subgroup differences was not significant (p=0.43).

FO vs. standard (no lipids): only one trial that used Omegaven was found, hence a subgroup comparison to non Omegaven studies was not possible (figure 5.2).

Stand-alone FO emulsion supplement vs. standard care: When examining the only trial of fish oils in which the control group received no IV soybean oil, no effect was seen on infections (Hall 2014, RR 0.60, 95% CI 0.16-2.29; p=0.45; no figure shown).

Hospital LOS:

Overall omega-6 fatty acid reducing strategy: When the 6 studies that used an omega-6 fatty acid sparing strategy were aggregated, the use of a lower omega-6 fatty acid emulsion was associated with a significant reduction in hospital LOS (WMD -6.88, 95% CI -11.27, -2.49, p=0.0.002, test for heterogeneity I²=20%; figure 6.1).

In subgroup analyses, **SO/OO** vs **SO/MCT** or **SO** had no significant effect on hospital LOS (WMD -6.80, 95% CI -19.17, 5.57, p=0.28, test for heterogeneity I²= 0%; figure 3.2). A trend towards shorter hospital LOS was observed with **FO** enriched **PN** vs. **SO** or **SO/MCT** or **SO/OO** (WMD -5.93, 95% CI -13.13, 1.27, p=0.11, test for heterogeneity I²= 51%; figure 6.1). The test for subgroup differences was not significant (p=0.90).

Omegaven vs. other fish oils:

FO enriched PN: When the data from 2 studies of Omegaven were aggregated, there was no effect on hospital length of stay (WMD -5.75, 95% CI -14.61, 3.11; p=0.20, test for heterogeneity I²=61%; figure 6.2) and a similar lack of effect was seen in the aggregated data from the two studies of other fish oil emulsions (WMD -12.87, 95% CI -42.65, 16.91, p=0.40, test for heterogeneity I²=92%; figure 3.3). Test for subgroup differences was not significant (p=0.65).

FO vs. standard (no lipids): all three studies used Omegaven, hence a subgroup comparison to non Omegaven studies was not possible. **Stand-alone FO emulsion supplement vs. standard care:** Fish oil emulsions had no effect on hospital LOS when compared to standard care (WMD = 0.78, 95% CI -2.89, 4.46, p=0.68, test for heterogeneity I²= 0%; figure 6.3).

ICU LOS

Overall omega-6 fatty acid reducing strategy: When all 12 studies that used an omega-6 fatty acid sparing strategy were aggregated, the use of a lower omega-6 fatty acid emulsion was associated with a trend towards a reduction in ICU LOS (WMD -1.94, 95% CI -4.41, 0.52, p=0.12, test for heterogeneity I²=83%; figure 7.1).

In subgroup analysis, SO/MCT or SO/OO vs SO had no effect on ICU LOS (WMD 1.74, 95% CI -2.17, 5.66, p=0.38, test for heterogeneity I^2 = 50%; figure 7.2); however, FO-containing PN vs SO or SO/MCT or SO/OO signifine antly reduced ICU LOS (WMD -3.53, 95% CI -6.16 to -0.90, p=0.009, I^2 = 82%; figure 7.2) There was a significant difference between the two subgroups (p=0.03).

SO/MCT vs SO: No difference in ICU LOS between the two groups (WMD 3.03, 95% CI -2.02, 8.07, p=0.24; figure 7.1).

SO/OO vs. SO/MCT or SO: When the data from the two studies of olive oil emulsions vs SO/MCT or SO were aggregated, olive oil emulsions had no effect on ICU length of stay (WMD -2.09, 95% CI -12.17, 8.00, p=0.69, test for heterogeneity I²=55%; figure 7.1).

FO containing PN vs. SO or MCT/SO or OO/SO: When the data from the eight studies of fish oil emulsions vs SO+ MCT or SO were aggregated, a significant reduction in ICU LOS was observed in the fish oil group (WMD -3.53, 95% CI -6.16 to -0.90, p=0.009, I²= 82%; figure 7.1).

Omegaven vs. other fish oils:

FO enriched PN: When the data from 4 studies of Omegaven were aggregated, there was a trend towards reduction in ICU length of stay (WMD -3.15, 95% CI -6.89, 0.59, p=0.10, test for heterogeneity I²=79%; figure 7.3). Similarly, when the data were aggregated from the four studies of other fish oil emulsions, a trend towards reduction in ICU LOS was observed (WMD -3.81, 95% CI -7.96, 0.34, p=0.07, test for heterogeneity I²=75%; figure 7.3). Test for subgroup differences was not significant (p=0.82).

FO vs. standard (no lipids): all four studies used Omegaven, hence a subgroup comparison to non Omegaven studies was not possible. **Stand-alone FO emulsion supplement vs. standard care:** When these trials were statistically aggregated, there was a trend towards reduced ICU LOS (WMD -1.38, 95% CI –4.11, 1.34, p=0.32; test for heterogeneity I²=52%; figure 7.4).

Ventilator days:

Overall omega-6 fatty acid reducing strategy: A trend towards shoter duration of ventilation was found with Omega-6 fatty acid sparing strategies (WMD -0.87, 95% CI -1.82, 0.07, p=0.07, test for heterogeneity I²=52%; figure 8.1).

In subgroup analyses, SO/MCT os SO/OO vs SO were associated with a significant reduction in ventilator days (WMD -3.26, 95% CI -5.32, -1.20, p=0.002, test for heterogeneity I^2 = 0%; figure 8.2) while FO-containing PN had no effect on ventilator days (WMD -0.31, 95 % CI -1.07, 0.45, p=0.42, test for heterogeneity I^2 = 39%; figure 8.2). The test for subgroup differences were significant (p=0.009).

SO/MCT vs SO: Only one study comparing SO+MCT to SO reported duration of ventilation and a significant reduction duration of mechanical ventilation in the SO+MCT group was observed (RR -3.30, 95% CI -5.39, -1.21, p=0.002; figure 8.1).

SO/OO vs. SO/MCT or SO: Only one study reported this outcome, and the use of olive oil emulsions had no effect on the duration of mechanical ventilation (WMD -2.00, 95% CI -13.92, 9.92, p=0.74; figure 8.1).

FO containing PN vs. SO or SO/MCT or SO/OO: When the data from the six studies of fish oils were aggregated, no effect on duration of mechanical ventilation was observed (WMD -0.31, 95% CI -1.07, 0.45, p=0.42, test for heterogeneity I²=39%; figure 8.1).

Omegaven vs. other fish oils:

FO enriched PN: When the data from 3 studies of Omegaven were aggregated, there was no effect on ventilator days (WMD -0.87, 95 % CI -2.37, 0.63, p=0.26, test for heterogeneity I²=35%; figure 8.3). Similar signals were seen when the three studies of other fish oil emulsions, were pooled (WMD 0.28, 95% CI -0.32, 0.88, p=0.36, test for heterogeneity I²=0%; figure 8.3). Test for subgroup differences was not significant (p=0.16).

FO vs. standard (no lipids): both studies that reported on ventilator days used Omegaven, hence a subgroup comparison to non Omegaven studies was not possible.

Stand-alone FO emulsion supplement vs. standard care: When these two trials were statistically aggregated, no effect on ventilator days was observed (WMD 1.98, 95% CI –2.36, 6.31, p=0.37; test for heterogeneity I²=0%; figure 8.4).

Other outcomes:

SO/MCT vs SO: A significant improvement in nutritional parameters (i.e., nitrogen balance, retinol binding protein, prealbumin) was observed in the groups receiving SO + MCT in some of the studies (Garnacho-Montero 2002, Lindgren 2001) and a significant reduction in the time of weaning was seen in one study (Iovinellei 2007).

SO/OO vs. SO/MCT or SO: No differences were found for multiple organ dysfunction score (Garcia-de-Lorenzo 2005) or other nutritional outcomes (Pontes-Arruda 2013, Umpierrez 2012)

FO containing PN vs. SO or SO/MCT or SO/OO: The use of FO was associated with a reduction in the need for surgery due to a subsequent septic episode when compared to LCT (p=0.010, Grecu 2003). Wang 2009 reported a reduction in the need for surgery for pancreatic necrosis in the group receiving FO, but this was not statistically different. There was a trend towards a reduction in catheter related blood stream infections in the group receiving fish oils (p=0.10, Friesecke 2008) and better gas exchange (Barbosa 2010). Singer 2021 reported a higher % patients tolerating EN alone at day 6 and higher catecholamine treatment free days in the omega 3 supplemented EN+PN group (p=0.34 and 0.05 respectively).

Conclusions: In critically ill patients,

- 1) Omega-6 FFA reducing strategies, also known as SO sparing strategies,
 - a. are not associated with a significant reduction in overall, ICU or hospital mortality, but a trend towards lower 28-day mortality was observed
 - b. are associated with a reduction in hospital LOS.
 - c. may be associated with a reduction in ICU LOS and duration of mechanical ventilation
 - d. have no effect on infections
- 2) SO/MCT emulsions, compared to SO, have no effect on mortality, infections, ICU or hospital length of stay in critically ill patients. There may be a significant reduction in duration of mechanical ventilation associated with SO/MCT but data points are too sparse to be sure (1 trial).
- 3) OO containing emulsions, compared to SO/MCT or SO,
 - a. have no effect on mortality or ICU/hospital LOS or duration of mechanical ventilation.
 - b. may be associated with increased infections
- 4) FO containing PN vs. SO or MCT/SO or OO/SO:
 - a. are not associated with a significant reduction in overall, ICU or hospital mortality but a trend towards lower 28-day mortality was observed
 - b. are associated with a significant reduction in infectious complications and ICU LOS.
 - c. may be associated with a reduction in duration of mechanical ventilation
 - d. have no effect on hospital LOS
- 5) Stand-alone FO emulsion supplement vs. standard care
 - a. is associated with a reduction of 28-day mortality and a trend towards reduction in overall and hospital mortality/
 - b. may be associated with a reduction in ICU LOS
 - c. have no effect on ICU mortality, infectious complications, duration of mechanical ventilation, or hospital LOS.
- 6) Compared to SO/MCT or SO/OO, FO-containing lipid emulsions
 - a. are associated with a significant reduction in infectious complications and ICU LOS
 - b. have no impact on mortality, hospital LOS and ventilator days.
- 7) Compared to non-Omegaven containing PN or IV nutritional strategies, Omegaven containing PN or IV strategies
 - a. May be associated with a significant reduction in mortality.

Level 1 study: if all of the following are fulfilled: concealed randomization, blinded outcome adjudication and an intention to treat analysis. **Level 2 study**: If any one of the above characteristics is unfulfilled.

Critical Care Nutrition: Systematic Reviews Jan 2022

Table 1. Randomized trials evaluating type of lipids (PN) in critically ill patients

Study	Population	Methods (score)	Intervention	Mortalit	y # (%)†	Infections # (%)‡		
			(A) SO/MCT vs. SO					
1) Nijveldt 1998	ICU, septic surgical patients, trauma N=20	C.Random: not sure ITT: yes Blinding: double (9)	ITT: yes + Intralipid (100% SO) Not specified 2/12 (17) Not specified 1/8 (13)		Not specified Not specified NR		SO NR
