4.1 (a) EN composition: Diets supplemented with arginine and select other nutrients*

January 31st 2009

Recommendation:

Based on 4 level 1 studies and 18 level 2 studies, we recommend that diets supplemented with arginine and other select nutrients* not be used for critically ill patients.

Discussion: The committee noted the lack of a treatment effect with respect to mortality and infections. These results are similar to those in a recent meta-analysis of immunonutrition in ICU, trauma and burn patients (1) (Marik and Zaloga 2008). The committee noted the results of the subgroup analysis, which shows that in higher quality studies, diets supplemented with arginine and other nutrients had no effect on mortality whereas in lower quality studies there was a trend towards a reduction in mortality. In light of the potential harm (increased mortality) associated with the use of diets supplemented with arginine and other nutrients, the reduction in length of stay and mechanical ventilation is difficult to interpret. Given the possible harm in septic patients (Bower, Ross, Bertolini) and the increased costs, the committee decided to recommend against their use in critically ill patients.

(1) Marik PE, Zaloga GP. Immunonutrition in critically ill patients: a systematic review and analysis of the literature. Intensive Care Med. 2008 (11):1980-90.

Value	Definition	Score 0, 1, 2 or 3
Effect size	Magnitude of the absolute risk reduction attributable to the intervention listeda higher score indicates a larger effect size	0, 1, 2 01 3
Confidence interval	95% confidence interval around the point estimate of the absolute risk reduction, or the pooled estimate (if more than one trial)a higher score indicates a smaller confidence interval	1
Validity	Refers to internal validity of the study (or studies) as measured by the presence of concealed randomization, blinded outcome adjudication, an intention to treat analysis, and an explicit definition of outcomesa higher score indicates presence of more of these features in the trials appraised	2
Homogeneity or Reproducibility	Similar direction of findings among trialsa higher score indicates greater similarity of direction of findings among trials	2
Adequacy of control group	Extent to which the control group represented standard of care (large dissimilarities = 1, minor dissimilarities=2, usual care=3)	3
Biological plausibility	Consistent with understanding of mechanistic and previous clinical work (large inconsistencies =1, minimal inconsistencies =2, very consistent =3)	2
Generalizability	Likelihood of trial findings being replicated in other settings (low likelihood i.e. single centre =1, moderate likelihood i.e. multicentre with limited patient population or practice setting =2, high likelihood i.e. multicentre, heterogenous patients, diverse practice settings =3.	2
Low cost	Estimated cost of implementing the intervention listeda higher score indicates a lower cost to implement the intervention in an average ICU	2
Feasible	Ease of implementing the intervention listeda higher score indicates greater ease of implementing the intervention in an average ICU	2
Safety	Estimated probability of avoiding any significant harm that may be associated with the intervention listeda higher score indicates a lower probability of harm	1

The term "Immune-enhancing diets" has been used to describe products that have immune-modulating properties such as arginine, glutamine, omega-3 fatty acids, and others. There are several commercially available enteral feeding products that contain varying amounts of arginine in combination with other immune modulating nutrients. Since arginine is the common ingredient across these various formulas, we elected to describe this section as "Diets supplemented with Arginine and other select Nutrients".

* (refer to tables for specific nutrients)

4.1 (a) EN composition: Diets Supplemented with Arginine and Other Select Nutrients

January 31st 2009

Question: Compared to standard enteral feeds, do diets supplemented with arginine and other nutrients result in improved clinical outcomes in critically ill patients?

Summary of Evidence: There were 22 studies reviewed, 4 level 1 studies and 18 level 2 studies. The data from the Bertolini study was not included in the meta- analysis as the control feed was parenteral nutrition, not an enteral formula. In one recent study (Beale 2008), the results were confounded by having two interventions combined in the experimental group (arginine and glutamine).

Mortality: All 22 studies reported on mortality and when the results of the 21 studies (Bertolini excluded) were aggregated, there was no effect on mortality (RR 1.06 95% CI 0.93, 1.20 p= 0.40) (figure 1). A subgroup analysis of high quality studies (score \geq 8) vs. low quality studies (score \leq 8) showed that in higher quality studies, diets supplemented with arginine and other nutrients were associated with a trend towards a reduction in mortality (RR 1.10 95% CI 0.95, 1.26, p =0.20) (figure 2), whereas in lower quality studies diets supplemented with arginine and other nutrients were associated with a trend towards a reduction in mortality (RR = 0.75, 95 % CI 0.49, 1.15, p = 0.19) (figure 3). The difference between these two subgroups was not statistically significant (p = NS). When the studies of trauma (RR 0.98, 95 % CI 0.49, 1.96, p = 0.96) vs. non-trauma patients (RR 1.07, 95% CI 0.89, 1.30, p =0.47) were compared, there were no differences in mortality (figures 4,5).

Infections: Based on the 13 studies that reported on infectious complications, there was no difference in the rate of infectious complications (RR 0.99 95% CI, 0.85,1.15, p = 0.88) (figure 6). Subgroup analysis also showed no differences in infectious complications when high quality studies (RR =0.99, 95% CI 0.83, 1.17, p = 0.87) (figure 7) were compared to lower quality studies (RR 0.97, 95% CI 0.65,1.45, p = 0.9) (figure 8) and when studies of trauma patients (RR = 0.86, 95 % CI 0.52, 1.42, p = 0.55) were compared to studies of non-trauma patients (RR 1.00, 95%CI 0.86, 1.16, p = 0.96) (figures 9,10).

LOS, Ventilated days: Diets supplemented with arginine and other nutrients were associated with a trend towards a reduction in hospital length of stay (WMD -2.40 95% CI -5.90, 1.09, p =0.18) (figure 11), a significant reduction on ICU length of stay (WMD -1.74, 95%CI -3.18, 0.30, p =0.02)* and a significant reduction in mechanical ventilation (WMD -1.41, 95%CI -2.85, 0.04, p =0.06)* (figures 12, 13).

* Denotes the presence of statistical heterogeneity (p< 0.05).

Conclusions:

- 1) Diets supplemented with arginine and other nutrients overall have no effect on mortality.
- 2) Diets supplemented with arginine and other nutrients have no effect on rate of infectious complications in critically ill patients.

3) Diets supplemented with arginine and other nutrients may possibly reduce hospital length of stay, ICU length of stay and mechanical ventilation.

Level 1 study: if all of the following are fulfilled: concealed randomization, blinded outcome adjudication and an intention to treat analysis. **Level 2 study:** If any one of the above characteristics are unfulfilled

TOPIC: 4.1 (a) Composition of EN: Diets with arginine and other nutrients

Article inclusion log

Criteria for study selection

Type of study: RCT or Meta-analysis

Population: Critically ill, ventilated patients (no elective surgery patients)

Intervention: EN

Outcomes: Mortality, LOS, QOL, functional recovery, complications, cost. Exclude studies

with only biochemical, metabolic or nutritional outcomes.
