

### 10.4.a. Optimal glucose control: Insulin therapy

March 2013

**2013 Recommendation:** *Based on 26 level 2 studies, we recommend that hyperglycemia (blood sugars > 10 mmol/L) be avoided in all critically ill patients and we recommend a blood glucose target of around 8.0 mmol/L (or 7-9 mmol/L), rather than a more stringent target range (4.4 to 6.1 mmol/L) or a more liberal target range (10 to 11.1 mmol/L).*

**2013 Discussion** The committee noted that with addition of 4 trials (Yu 2005, Savioli 2009, Annane 2009 and Arabi 2011) since the meta-analysis by Griesdale et al <sup>(1)</sup> and the removal of studies not felt to be in critically ill patients (stroke ICU, Bruno 2008), there was no changes in the treatment effect for mortality infections and the rating of the other values remained the same. Given the persistent signal that intensive insulin therapy is associated with a significant increase in the incidence of hypoglycemia, the committee agreed to recommend a range that avoided both high and low blood sugars.

**2009 Recommendation:** *We recommend that hyperglycemia (blood sugars > 10 mmol/L) be avoided in all critically ill patients. Based on the NICE-SUGAR study and a recent meta-analysis, we recommend a blood glucose target of around 8.0 mmol/L (or 7-9 mmol/L), rather than a more stringent target range (4.4 to 6.1 mmol/L) or a more liberal target range (10 to 11.1 mmol/L).*

**2009 Discussion:** The committee noted the results of the recently published meta-analysis <sup>(1)</sup> and the results of the largest multicentre trial, the NICE-SUGAR study<sup>(2)</sup>. Whilst the meta-analysis noted a possible treatment benefit with tight glycemic control in surgical patients, this was not supported by the subgroup analysis in the NICE-SUGAR study which showed a significant increase in mortality in surgical patients. Furthermore, the NICE-SUGAR trial is more likely to be generalizable to Canada or other settings that use a predominantly enteral-based feeding approach. It was also noted that the positive signal in surgical patients in the CMAJ meta-analysis was primarily driven by two studies, the reproducibility of these results was considered questionable given the nature of the accompanying nutritional strategy used in one study<sup>(3)</sup> and the single centre nature of the other study<sup>(4)</sup>. Given this the committee reversed its prior recommendation and agreed that tight glycemic control (4.4 to 6.1 mmol/L) is no longer recommended for surgical patients. Instead the committee recommended that the target range be the resultant blood glucose range in the NICE SUGAR study i.e. 8.0 mmol/L (7.0-9.0 mmol/L). This range avoids hyperglycemia, while minimizing the risk of both iatrogenic hypoglycemia and other harms associated with a lower blood glucose target. The committee noted that insulin protocols (either paper or computerized) were used to achieve glycemic control in the reviewed studies but did not make a recommendation as to how best to achieve good glycemic control.

## Semi Quantitative Scoring

Value	Definition	2009 Score (0,1,2,3)	2013 Score (0,1,2,3)
Effect size	Magnitude of the absolute risk reduction attributable to the intervention listed--a higher score indicates a larger effect size	0	0 (mortality) 1 (infection)
Confidence interval	95% confidence interval around the point estimate of the absolute risk reduction, or the pooled estimate (if more than one trial)--a higher score indicates a smaller confidence interval	1	1
Validity	Refers to internal validity of the study (or studies) as measured by the presence of concealed randomization, blinded outcome adjudication, an intention to treat analysis, and an explicit definition of VAP--a higher score indicates presence of more of these features in the trials appraised	2	2
Homogeneity or Reproducibility	Similar direction of findings among trials--a higher score indicates greater similarity of direction of findings among trials	2	1
Adequacy of control group	Extent to which the control group represented standard of care (large dissimilarities = 1, minor dissimilarities=2, usual care=3)	2	2
Biological plausibility	Consistent with understanding of mechanistic and previous clinical work (large inconsistencies =1, minimal inconsistencies =2, very consistent =3)	2	2
Generalizability	Likelihood of trial findings being replicated in other settings (low likelihood i.e. single centre =1, moderate likelihood i.e. multicentre with limited patient population or practice setting =2, high likelihood i.e. multicentre, heterogenous patients, diverse practice settings =3.	3	3
Low cost	Estimated cost of implementing the intervention listed--a higher score indicates a lower cost to implement the intervention in an average ICU	3	3
Feasible	Ease of implementing the intervention listed--a higher score indicates greater ease of implementing the intervention in an average ICU	2	2
Safe	Estimated probability of avoiding any significant harm that may be associated with the intervention listed--a higher score indicates a lower probability of harm	1	1

### 10.4.a. Optimal glucose control: Insulin therapy

March 2013

**Question:** Does tight blood sugar control result in better outcomes in the critically ill adult patient?

**Summary of evidence:** There was a recent meta-analysis of 26 randomized controlled trials (Greisdale 2009) that was reviewed. Subsequent to the publication of the meta-analysis, the data from two of the included trials (Bilotta 2007 and 2008) were replaced by the data from a more recent trial (Bilotta 2009) and 3 new studies were reviewed (Savioli 2009, Annane 2010, Arabi 2011). All 26 trials included were level 2 studies. Of the 26 trials, four of these were in surgical patients (Van den Berghe 2001, Grey 2004, He 2007 and Bilotta 2009), 14 were in mixed ICUs, and 10 were in medical patients. The target ranges of blood sugars in the intervention group varied from 4.0–6.0 to 4.4–8.3 mmol/L. In the Annane 2010 study, all patients were on steroids (compared to only 50% this population receives steroids), hence a sensitivity analysis was done without this study. One study compared intensive insulin therapy plus a carbohydrate restricted to maintain diet blood sugars < 10 mmol/L plus to intensive insulin therapy to maintain blood sugars < 8 mmol/L (de Azevedo 2010) and this study is summarized in the section 10.4 b Optimal glucose control: Carbohydrate restricted formula plus insulin therapy.

**Mortality:** When the data from the studies were aggregated, intensive insulin therapy was associated with a trend towards a reduction in overall mortality (RR 0.91, 95% CI 0.82, 1.02,  $p=0.10$ , heterogeneity  $I^2=41\%$ ; figure 1a). When a sensitivity analysis was done excluding the Annane 2010 study, this trend towards a reduction in overall mortality remained. (RR 0.90, 95% CI 0.80, 1.01,  $p=0.06$ , heterogeneity  $I^2=41\%$ ; figure 1b). The Bilotta 2009 study was not included in the analyses since it only reported mortality at 6-months.

**Infections:** Only 6 studies reported the total number of infections per group and when the data from these studies were aggregated, intensive insulin therapy had no effect on the number of infections (RR 0.89, 95% CI 0.73, 1.09,  $p=0.26$ , heterogeneity  $I^2=55\%$ ; figure 2a); the result was the same when the Van den Berghe 2001 study that provided high IV glucose was excluded from the analysis (RR 0.96, 95% CI 0.84, 1.10,  $p=0.59$ , heterogeneity  $I^2=9\%$ ; figure 2b).

**Length of stay:** When the data from the 7 studies that reported ICU length of stay as a mean  $\pm$  standard deviation were aggregated, intensive insulin therapy was associated with a significant reduction in ICU length of stay (WMD -1.78, 95% CI -2.47, -1.09,  $p<0.00001$ , heterogeneity  $I^2=0\%$ ; figure 3a); the result was the same when both Van den Berghe studies were excluded from the analysis (WMD -1.46, 95% CI -2.73, -0.19,  $p=0.02$ , heterogeneity  $I^2=18\%$ ; figure 3b). When the data from the 4 studies that reported hospital length of stay as a mean  $\pm$  standard deviation were aggregated, intensive insulin therapy had no effect on hospital length of stay (WMD -1.07, 95% CI -3.68, 1.54,  $p=0.42$ , heterogeneity  $I^2=0\%$ ; figure 4a); the result remained the same when the two Van den Berghe studies were excluded from the analysis (WMD -1.71, 95% CI -13.85, 10.43,  $p=0.78$ , heterogeneity  $I^2=0\%$ ; figure 4b).

**Duration of ventilation** When the data from the 6 studies that reported duration of ventilation as a mean  $\pm$  standard deviation were aggregated, intensive insulin therapy was associated with a significant reduction in the number of ventilation days (WMD -1.41, 95% CI -2.58, -0.23,  $p=0.02$ , heterogeneity  $I^2=79\%$ ; figure 5a); however when the two Van den Berghe studies were excluded from the analysis, intensive insulin therapy was associated with a trend towards a reduction in the number of ventilation days (WMD -0.99, 95% CI -2.36, 0.39,  $p=0.16$ , heterogeneity  $I^2=63\%$ ; figure 5b).

**Hypoglycemia:** When the data from the 18 studies that reported hypoglycemic events were aggregated, intensive insulin therapy was associated with a significant increase in incidence of hypoglycemia (RR 3.19, 95% CI 1.81, 5.60,  $p<0.0001$ , severe heterogeneity,  $I^2=94\%$ ; figure 6a); the result was the same when the Van den Berghe 2001 study was excluded from the analysis (RR 3.03, 95% CI 1.71, 5.40,  $p=0.0002$ , severe heterogeneity,  $I^2=94\%$ ; figure 6b).

### Conclusions:

- 1) Intensive insulin therapy is associated with a trend towards a reduction in overall mortality.
- 2) Intensive insulin therapy has no effect on infections.
- 3) Intensive insulin therapy may be associated with a significant reduction in ICU length of stay and duration of ventilation.
- 4) Intensive insulin therapy has no effect on hospital length of stay.
- 5) Intensive insulin therapy is associated with a significant increase in hypoglycemia.

Table 1. Randomized studies evaluating intensive insulin therapy in critically ill patients

Study	Population	Methods (score)	Intervention	Mortality # (%)		Infections # (%)‡	
				Intensive Insulin	Conventional Insulin	Intensive Insulin	Conventional Insulin
1) Van Den Berghe 2001	ICU ventilated (mainly surgical) N=1548	C.Random: yes ITT: yes Blinding: no (11)	Intensive insulin therapy (bl. glucose range between 4.4 –6.1 mmol/L) vs. Conventional (bl. glucose range between 10-11.1 mmol/L)	Intensive Insulin ICU 35/765 (5) Hospital 55/765 (7)	Conventional Insulin ICU 63/783 (8) Hospital 85/783 (11)	Intensive Insulin 32/765 (4)	Conventional Insulin 61/783 (8)

C.Random: concealed randomization  
ITT: intent to treat; NA: not available

‡ refers to the # of patients with infections unless specified  
\*\* RR= relative risk, CI= Confidence intervals

TNA: Total Nutrient Admixtures  
( ) : mean ± Standard deviation (number)

( - ) : median (range)  
NR: not reported

To convert values of glucose to mg/dL, multiply mmol/L X 18.01; to convert to mmol/L, multiply mg/dL x 0.05551
